## An Autonomous DataFactory

As a method of forming and purifying the pharmaceutically relevant polymorph<sup>[1]</sup>, crystallisation of an active pharmaceutical ingredient (API) is a key step in pharmaceutical manufacturing. Determining an industrial-relevant approach for API crystallisation can be resource-intensive as a candidate crystallisation process is constrained by and assessed against industrial relevant solubilities, downstream processing practicalities, and regulator-determined Critical Quality Attributes (CQA) of the API<sup>[2-4]</sup>.

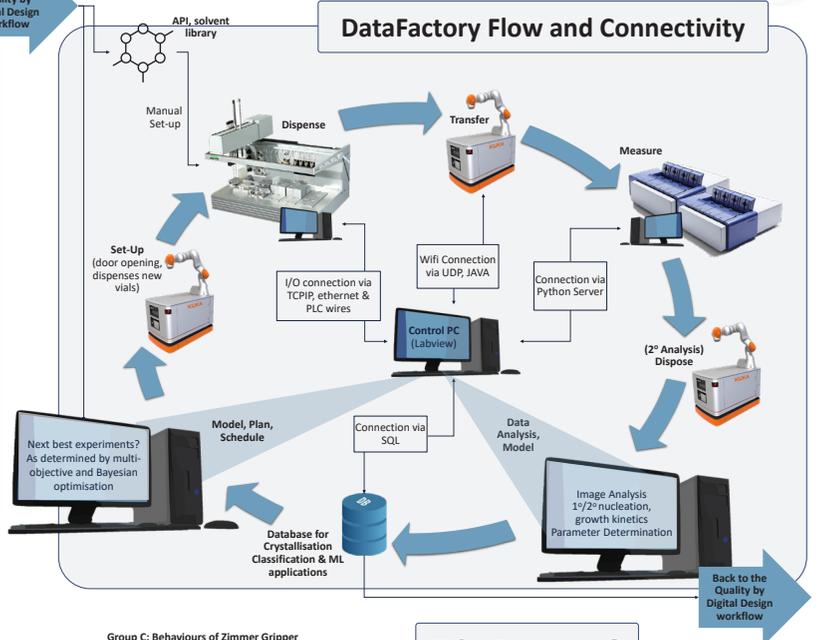

The DataFactory at the CMAC aims to use high throughput small-batch cooling crystallisation experiments coupled with machine learning to reduce the time and material costs associated with this process. Alongside the development of automated data collection, we are incorporating an autonomous decision-making system to optimize the small-batch cooling crystallisation of APIs and calculate relevant kinetic parameters to inform larger-scale experiments.

Here we present the steps we're taking to integrate and automate different platforms via a cobot and a central control PC, in addition to the beginnings of the database that will be the foundation of a crystallisation classification system.

## Introducing the Cobot

## DataFactory Flow and Connectivity

## Why Automate?

- 'Out of hours' operation of research equipment
- Enables researchers to reallocate time previously spent performing routine experiments
- Consistent, reliable and reproducible results across many API/solvent systems
- Hands-off nature of the system enables pharmaceutical development during pandemics

## A Database for a Crystallisation Classification System

This work is establishing a consistent and reliable database for dozens of API-solvent systems. While current data collection still requires manual loading, unloading, and human-made decisions, integrating the cobot with programming logic and autonomous decision-making will accelerate this data collection. The resulting dataset will be used with machine learning to predict industrial relevant experimental approaches for the crystallisation of future APIs.

AS	Antisolvent*
N	Not run yet
PM	Phobic Material
Y-G	Yes - Good (in desired solubility range**, no needles)
Y-A	Yes - Acceptable (near desired solubility*** range limits)
WS	in OR near solubility range**** but Wrong Shape (i.e. needles)
DNN	in OR near solubility range**** but Did Not Nucleate
OO	in OR near solubility range**** but Oiled Out
TS	Too Soluble

**Solvent screening:** thermocycling (x3) of ~2 - 7 mL of API and solvent to determine clear and cloud points. Data below.  
**Kinetic parameter estimation** (results not shown here): dissolution followed by crash cooling to an isothermal hold (x3) of ~2 mL of API and solvent.  
 All solubility and kinetic experiments done by Thomas Pickles  
 $T_1 > \sim 50$  °C and  $T_2 < 50$  °C  
 \* Solubility < 5 g/L at  $T_1$   
 \*\* In desired solubility range: at temp  $T_1$ , solubility is 50-250 g/L AND at temp  $T_2$ , solubility is > 5 g/L  
 \*\*\* Near desired solubility range: at temp  $T_1$ , solubility is 5-50 g/L OR 250-500 g/L AND at temp  $T_2$ , solubility is > 5 g/L

The Solubility Database to date...

## Solvent \ Solute

Solvent \ Solute	Lamivudine	Aspirin	Ibuprofen	Ascorbic Acid	Salicylic Acid	Mannitol	Benzoic Acid	Sodium	Benzotate
