

**## contribution for SI on machines and measures##****Welcome in the machine. Human-machine relations and knowledge capture****Abstract**

This paper discusses new technologies in regards to their potential to capture workers' situated knowledge. Machines are said to substitute but also to contribute to the labour process in collaboration with human skill sets. 'Industry 4.0' became the policy-wide shorthand to describe the new quality of real time interconnectedness and feedback loops, known as cyber-physical systems (CPS) within industry and engineering sciences. Data flows generated in these systems are used to continuously improve work processes by extracting information down to the very micro level of neuroergonomics. In this process, workers' interactions with the system are extracted, fed back and processed for future use and improvement. The paper argues that in addition to the potential for extraction of new (bodily) knowledge, shifting skill use, and the potential for new forms of control, new technologies contain the potential to extract situated knowledge<sup>i</sup> owned by the worker and crucial for resistance and collective struggles.

**Introduction**

Recent debates on automation are beginning to show a pattern in regards to their claims. Machines are said to substitute but also to contribute to the labour process in collaboration with human skill sets. One strand dominating the Anglo-Saxon debate is based on assumptions about future labour markets and frames automation mainly as a substitute for

1  
2  
3 specific skill sets. Frey and Osborne in their now seminal paper in 2013, or in modified forms  
4  
5 (Arntz et al 2015), define jobs that are prone to automation assessing occupational skill mix  
6  
7 using definitions used for national labour markets. This explains partly why consultancy  
8  
9 firms like Deloitte and PWC have been quick in adopting the method to showcase how  
10  
11 specific sectors like retail and manufacturing are to see massive changes in different  
12  
13 countries. Change needs to be managed, and consultancy firms are positioning themselves  
14  
15 to offer their expertise. The consultancy-led debate sticks to technological fetishism, not  
16  
17 taking into account the underlying (organisational) social relations, and hence disconnects  
18  
19 from questions around the material likelihood of automation. They neglect decision making  
20  
21 processes, power relations (Howcroft & Taylor 2015; Wajcman 2017), let alone gender. Even  
22  
23 though there are new technologies at hand to increase job quality for nurses, e.g. assisting  
24  
25 robots to help carry frail people, the most implemented technologies focus on rationalising  
26  
27 nurses work even more (Hayes & Moore 2017), or using socially assistive robots to avoid the  
28  
29 human care work seen as necessary in aging societies. Another obvious omission in this  
30  
31 debate is the influence of national and sectoral path-dependency of technological  
32  
33 developments, or precedent investment in R&D, in short a Varieties of Capitalism inspired  
34  
35 approach to explain differences in levels of automation and future pathways.<sup>ii</sup> Even though  
36  
37 the World Development Report on the Changing Nature of Work delivers an insight into the  
38  
39 challenges countries are facing, still it is reporting on an aggregated level (World Bank 2019).  
40  
41 Last not least the integration of new technologies is by no means a plug and play situation,  
42  
43 so the question will be what about the labour needed to integrate new technologies  
44  
45 (Mateescu & Elish 2019) or to burden the non intended side effects in the realm of  
46  
47 precarious, exploitative work were 'artificial intelligence has fallen short' (Irani 2016:721,  
48  
49 2019). New technologies, we can summarise so far, will be available, but it remains unclear  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 what type of technology will become ubiquitous, what technology might be test trialled but  
4  
5 prove inefficient.  
6

7  
8  
9 As we can see the question what tasks, skills, or even occupations will be automatable is  
10  
11 contingent, but we can assume without being accused by technological determinism that  
12  
13 new technologies will be introduced sectorwide, setting new industrial standards – as we  
14  
15 have already seen with RFID chips. In this paper, I will not contribute to positivist sociology  
16  
17 and claim any predictive potential. Instead I will focus on changes in the relation between  
18  
19 humans and machines at work in regards to knowledge extraction. Over the last decades or  
20  
21 so, one significant change in the  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34

35 For my argument, I focus neither on on the dimensions are seen as quasi safe spaces for  
36  
37 human labour, and frame them in terms of knowledge.  
38  
39

40 , the related debates on the Internet of Things (IoT) are interesting in that they restricted  
41  
42 their predictions to machine-machine relations, and focused on the new potential to  
43  
44 connect every single physical object ('things') to the internet and hence with each other,  
45  
46 enabling machines to sense, to act, and to interact. It is here where the notion of '4.0'  
47  
48 comes in, integrating machine-machine interconnectedness with human-machine relations  
49  
50 and taking into account the social aspects of technological systems. In its original  
51  
52 institutional setting, the German industrial policy landscape, Industry 4.0<sup>iii</sup> is defined as  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 cooperative approach to actively steer and manage the next wave of automation (Pfeiffer  
4  
5  
6 2017b).

7  
8  
9 Since coined in 2011 in the German context, Industry 4.0 became a proxy for all types of  
10  
11 changes, covering all sectors, technologies, and seems to be applicable in the global context  
12  
13 from the gig economy to care work. The core claim is that in actively using the skill sets  
14  
15 available, in upskilling the existing workforce, and planning future skill ecosystems wisely,  
16  
17 automation will be a 'win win' situation. This national approach aligns the state, employer  
18  
19 associations, trade unions, and academic research institutions to transform the industrial  
20  
21 landscape. Trade unions supported this approach, as in the ideological heart of a 'successful'  
22  
23 transition lies the promise for a better-educated workforce, better jobs, and the hope for  
24  
25 increased job quality (Pfeiffer 2017a). However, the few publications based on empirical  
26  
27 evidence seem to support a technological fixation, with trade unions having a say on the  
28  
29 policy level, but workers voice vanishing in the white noise of machine talk (Butollo et al  
30  
31 2018).

32  
33  
34 Empirical research suggests more negative outcomes of the newest wave of automation,  
35  
36 with some claiming a new form of control coined 'cybernetic control' (Raffetseder et al  
37  
38 2017). A cybernetic system is understood as one in which data flows are generated within a  
39  
40 closed circuit and used to continuously improve processes by collecting and using  
41  
42 information for further prediction. In manufacturing for example, here understood in a  
43  
44 broad sense including factory-like environments like warehouses, a process of 'predictive  
45  
46 manufacturing' is enabled by the combination of analytical algorithms and data made  
47  
48 available for processing in cloud computing spaces. While in the common use of the cloud it  
49  
50 is reduced to its function of storing data, cloud computing and available services are the key  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 for the next generation of cyber collaboration and real time tracking. Cyber-physical  
4  
5 systems, the crucial defining difference between industry 3. And 4. have the potential to  
6  
7 create a coupled models, 'digital twin(s) of the real machine that operates with an  
8  
9 integrated knowledge from both data driven analytical algorithms as well as other available  
10  
11 physical knowledge' (Lee et al 2013:41). This approach is used to actively monitor machines  
12  
13 and with this human labour. Historically, data was generated e.g. for planning based on Just  
14  
15 In Time- systems, but the measurement took place in a way which was physically  
16  
17 disconnected from the workers. Although their output would be monitored, the micro  
18  
19 movements remained shielded from view. Human labour, as shown by  
20  
21 Labpour Process Theory inspired research, was in power of reflexive and subjective agency  
22  
23 where or when necessary, be it in the form of collaboration, misbehaviour, or resistance.  
24  
25 What we can observe now is that with machines are coming closer to the workers' micro  
26  
27 movements, the single workers' interactions with the system are extracted, fed back and  
28  
29 processed for future use and improvement. In addition to the potential for extraction of  
30  
31 new (bodily) knowledge, shifting skill use, and new forms of control, CPS contain the  
32  
33 potential to extract what can be described as tacit (Polanyi 1966) or situated knowledge,  
34  
35 owned by the worker and crucial for resistance and collective struggles.  
36  
37  
38  
39  
40  
41  
42  
43

44 In the following sections, I will discuss the extraction of worker's situated knowledge<sup>iv</sup>, their  
45  
46 tacit capital, emotions and affects. The aim is to re-visit the incorporation and absorption of  
47  
48 the human worker's knowledge. Contrary to the linear vision of technological development  
49  
50 underlying most debates so far, CPS re-connects the worker to the machine in a qualitatively  
51  
52 new fashion: Human labour neither is but an appendage, nor can it strive in new realms of  
53  
54 free time (Wending 2009) as suggested in the earlier debates on automation, seeing the  
55  
56 rise of system regulation (Kern & Schuman 1984) or symbol analysts (Reich 1991) , in both  
57  
58  
59  
60

1  
2  
3 waves described as unique and irreplaceable due to the human potential of thinking and  
4  
5  
6 problem solving.  
7  
8  
9

### 10 **Beyond the human machine divide. Machines and human companions**

11  
12  
13 Marx's depiction of the relation between the human and the machine throughout his works  
14  
15 can be roughly divided in a pessimistic and a more concrete utopian version. In *Capital*, with  
16  
17  
18 Marx analyses the worker as reduced to a 'mere appendage' or doing the residual drudgery  
19  
20  
21 work, when buying labour is cheaper than investing into machinery. In Marx's own words,

22  
23 "all methods for raising the social productiveness of labour are brought about at the  
24  
25 cost of the individual labourer; all means for the development of production  
26  
27 transform themselves into means of domination over, and exploitation of, the  
28  
29 producers; they mutilate the labourer into a fragment of a man, degrade him to the  
30  
31 level of an appendage of a machine, destroy every remnant of charm in his work and  
32  
33 turn it into a hated toil; they estrange from him the intellectual potentialities of the  
34  
35 labour process in the same proportion as science is incorporated in it as an  
36  
37  
38 independent power" (Marx 1975a [1887]).  
39  
40  
41

42  
43 The first part of the quote is in line with the negative potential of automation and the use of  
44  
45 technology under capitalism. The human-machine relation is one-sided and weighted in  
46  
47 favour of the machine becoming a tool to increase production but, this is important to keep  
48  
49 in mind, also a tool for domination over the workers. Marx then elaborates in detail what he  
50  
51 elsewhere (Marx 1975b [1845/46]) conceptualised as alienation on different levels: from the  
52  
53 product, the production, species essence, and other workers. One can conclude that the  
54  
55 worker's 'intellectual potentialities' diminish in relation to the science incorporated. Marx is  
56  
57  
58 referencing the important connection between sciences and the development of  
59  
60

1  
2  
3 technologies, with science becoming an independent power. In his quote, he makes one of  
4  
5 the first and remarkable critiques on how the new and 'enlightened' sciences (not  
6  
7 technologies!) are quickly incorporated into the capitalist mode of production. Marx  
8  
9 presents a vision of sciences stemming from what later is called science-based industries,  
10  
11 with the chemical industry as the first mover in this respect, establishing new links: The rise  
12  
13 of state funded scientific research in universities, the integration of research and  
14  
15 development into companies (or, like in the chemical industry, being the driver of the  
16  
17 industry), and the bonds between the two. The linear idea of knowledge production never  
18  
19 fully encapsulated the human skill involved, or could predict how workers would use them,  
20  
21 and even the most elaborated Taylorist work system would not run without the tacit  
22  
23 knowledge of the workers. This optimistic idea of empowerment of the workers by an ever  
24  
25 increasing automated work organisation is emphasised by Marx. In the Fragment on  
26  
27 Machines in *Grundrisse*, Marx offers the utopian vision of technology freeing up time, with  
28  
29 machines mirroring advances in sciences and hence literally incorporating while at the same  
30  
31 time allowing for what he called the general intellect of the worker to rise (Marx [1858]). In  
32  
33 the post-operaist perspective, the then remaining immaterial labour (affective, emotional,  
34  
35 but also control and regulation of the machines) would be disconnected from measured (or:  
36  
37 measurable) time, with value creation collapsing into fixed capital. This process would be  
38  
39 crucial to build on the hope for the 'social worker' and the rise of a new revolutionary  
40  
41 subject. While the debate around the general intellect and immaterial labour is advanced  
42  
43 (see Thompson & Briken 2017 for a critical discussion), for my argument I am more  
44  
45 interested in the way in which Marx conceptualises the relation between sciences and  
46  
47 human labour, knotted together by knowledge. As mentioned earlier, one crucial point is  
48  
49 not control for the sake of control (and often confused with surveillance). Control in the  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Marxist version is a broader concept including the control with regards to knowledge.  
4  
5 Wendling (2011) made an interesting point in carefully reading through Marx's work in  
6  
7 regards to his vision on the role of sciences. The ownership of knowledge on one hand  
8  
9 seems to lie fully in the hands of what Taylor described as 'scientific management'. This  
10  
11 version of separating the human worker from the machine within the labour process  
12  
13 resonates with many of the debates concerned with the introduction of new technologies at  
14  
15 work. The polarisation thesis (Blauner 1964; Kern& Schumann 1970), or the (contested)  
16  
17 deskilling thesis (Braverman 1974) agreed on the fact the job design of low skilled routine  
18  
19 work in manufacturing would lack autonomy and reduce worker's cognitive powers  
20  
21 (Spencer 2018:2), while highly automated workplaces would have the potential to use  
22  
23 different skill sets. In the 1980s, the notion of system regulation captured this idea  
24  
25 suggesting workers would be freed from direct machine related tasks. The question about  
26  
27 the 'End of division of labour', as launched by the German industrial sociologists Kern and  
28  
29 Schuman in 1984, resonated with 'flexible specialisation' (Piore&Sabel 1984) and other far  
30  
31 reaching predictions based on case study research, leading to the idea of creating  
32  
33 automation winners and losers, a notion that tends to guide media coverage and policy  
34  
35 advice until today. The rather reductionists and binary perspective on the development on  
36  
37 human machine relation reflects how, within the sociology of work, so far machines and  
38  
39 human are still predominantly conceptualised in a way that seems to allow to objectively  
40  
41 assess and separate skills use from the tool. Or, in other words, as if the boundaries  
42  
43 between the human worker and the machine tasks can be set based on scientific  
44  
45 measurement and calculation.  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 However, with and against Marx, his draft on the Fragment of Machines offers the option  
4  
5 for a more nuanced reading, taking into account the excess knowledge deriving from, but at  
6  
7 the same time and more important for the sake of this argument, created within the  
8  
9 interaction between human labour and the machine: From an engineering or management  
10  
11 perspective, these pockets of autonomy and discretion are seen as the cause for errors in an  
12  
13 objectified 'rationale' workplace, or as flaws in the workings of technology; labour process  
14  
15 theory conceptualises the potential for some forms of resistance and organisational  
16  
17 misbehaviour around situated knowledge (Ackroyd & Thompson 2016; Thompson 2016);  
18  
19 literature inspired by post-operaist perspectives tend to focus on the immaterial aspect of  
20  
21 labour, and emphasise emotional and affective labour to allow for the workings of the  
22  
23 machinery to their full capacity. While these strands describe the human machine relations  
24  
25 in an opposing way, separating the human distinctively from the machine, it is worthwhile  
26  
27 to remind us of the workers' perception of the relation to the technologies. On one hand,  
28  
29 research on occupational and work identities have shown the relevance for workers'  
30  
31 identity but also for collective struggle and as part of workers' power (Briken 2018;  
32  
33 MacKenzie et al 2017). On the other, studies in the sociology of work and subjectivity have  
34  
35 long suggested that even in so called unskilled and routine work environments subjective  
36  
37 factors like 'emotions, sensations or impressions derived from personal experience' (Pfeiffer  
38  
39 2016:5) play an important role within the labour process. This specific strand of studies on  
40  
41 experienced-based work is partly overlapping with ideas around tacit knowledge. However,  
42  
43 the focus here is on the analytical level, focussing not on tacit knowledge in general but  
44  
45 more on what haraway has described as situated knowledge and the connected emotional  
46  
47 and affective encounter with technology, blurring in part the frontier between human and  
48  
49 machine. To give an example from the research in control rooms in the chemical industry  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 (the at that time called 'second reality of production', Waldhubel 1971). Here, researchers  
4  
5 found that sometimes workers would ignore an alarm; and how they would run  
6  
7 immediately the next day with the exact same alarm getting oof. When asked, the workers  
8  
9 would reply how they would 'sense there is something wrong'<sup>v</sup>. The Eigen-Sinn of the  
10  
11 machinery, with workers addressing the machinery as a quasi human, investing care and  
12  
13 emotions or even affect is what makes even routine assembly work prone to the  
14  
15 unpredictability of machines and humans, only understood by the human worker (Pfeiffer  
16  
17  
18  
19  
20  
21 2016).

22  
23  
24 The new management concepts discussed above focussed precisely on closing this  
25  
26 knowledge gap by switching from (individual) company suggestion schemes to (collective)  
27  
28 continuous improvement processes. A common feature of all variations of 'lean' or  
29  
30 Toyotism was to 'dig in the gold of worker's brains' and the connected responsabilisation of  
31  
32 workers and teams to improve their work environments. Instead of skills, human resources  
33  
34 management started focussing on workers' knowledge, and specifically the ones hidden so  
35  
36 far, labelled tacit knowledge (Polanyi 1966; Nonaka and Takeuchi 1995). The concepts  
37  
38 aimed at depicting the smallest potential for efficiency in the production system, are framed  
39  
40 them as incremental innovation processes, sold as a boost for job motivation and an  
41  
42 improvement in job quality, but further hopes for widening voice at work were curbed  
43  
44 quickly by management. Today, improvements delivered by semi-autonomous work groups  
45  
46 and individual workers are part of performance management schemes, and strong pressure  
47  
48 is put on workers to disclose their situated knowledge.  
49  
50  
51  
52  
53  
54  
55  
56

57 **Beyond control: Capturing situated knowledge.**  
58  
59  
60

1  
2  
3 The normalisation of incremental innovation from exceptional and expert tasks to daily  
4 routine on the assembly line was closely connected to the widespread integration of  
5 information technologies into companies in the 1990s. New forms of enterprise resource  
6 planning (like the then famous SAP R/3 software) gave firms the opportunity to coordinate  
7 all resources, information and activities needed to complete their processes, from order  
8 fulfilment, billing, human resource management, to production planning – but in real time  
9 and, if necessary, visible for everyone. This new mode of rationalisation coined ‘systemic’ in  
10 the German context enabled the organisations to focus on the entire value-added process,  
11 or, value chain. The point I want to highlight is the availability of ‘objectified’ measurement  
12 shape shifting the mode of control. The newly available real time data had the potential to  
13 put organisational units down to the very team level under the pressure of actual or fictive  
14 market forces (Döhl/Sauer 1994), changing the quality of performance management  
15 towards the ‘objectivation or de-subjectivation of performance politics’ (Döhl & Sauer  
16 1994:212, transl the author). The shift towards data-driven forms of control enabled a new  
17 time economy – known as Just In Time – ultimately intensifying work. The potential for  
18 measurement also enabled to encourage competition at group and individual workers  
19 level. In essence, workers no matter their skill levels, were subjected to more extensive and  
20 objectified forms of control. In line with Thompson’s (2003) analysis, this process can be  
21 covered with what Edwards (1979) characterised as technical and bureaucratic control, i.e.  
22 the capacity of the technology to pace and direct the entire production process and to  
23 objectify control. However, the inclusion of markets as controlling forces brought in at least  
24 a new legitimation stemming from outwith the organisation.

1  
2  
3 From the mid 1990s onwards, the potential to gather real time insight into all inter and intra  
4  
5 organisational processes increased exponentially. Benchmarking, i.e. comparing ever more  
6  
7 and sophisticated layers and levels of the labour process, teams with teams, but also with  
8  
9 industry wide metrics became standard and a newly normalised management function. The  
10  
11 increase in visualisation and transparency and the pressure on workers to integrate their  
12  
13 knowledge by continuously contributing to make their workspaces more efficient, hence to  
14  
15 add even more surplus value in the same amount of time, the real time data also turned  
16  
17 into a tool for workers' self control. Far from being 'chimeric', as suggested by a  
18  
19 poststructuralist reading of the labour process and control, workers know exactly the extent  
20  
21 to which they are controlled. Visualisation was one of the key changes on the shop floor,  
22  
23 rarely discussed in the debates around lean management and high performance work  
24  
25 systems. In car manufacturing, control panels operating in view above assembly lines, for  
26  
27 example, would indicate the real time outcome of each specific point or workplace at any  
28  
29 given time of production. Workers only needed to raise their heads to see how much they  
30  
31 had produced, what they were supposed to, and how their outcome matched compared to  
32  
33 other shifts that day, or that week. Continuous improvement in many of these work systems  
34  
35 became an integral part of performance management. The aim was to extract the workers'  
36  
37 situated knowledge, and hence to eliminate the 'waste' embedded in workers' reflexive  
38  
39 agency. Although spaces for resistance and organisational misbehaviour would be harder to  
40  
41 sustain, labour process oriented research still opposes for good reasons the idea of  
42  
43 technology determining every pore of the working day. Surveillance might have become  
44  
45 ubiquitous, but the connected forms of control still relied very much on feedback on  
46  
47 outcomes, hence on static data not the process. The direct impact of technology on the  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 worker and vice versa was as yet unopened Pandora's Box, and improving performance  
4  
5 relied either on planning outside the workplace, or the active collaboration of workers.  
6  
7

8 It is important here to distinguish between different management interventions to improve  
9  
10 performance and increase the surplus value of human labour, one focussing on skills  
11  
12 utilisation, the other focussing on knowledge extraction. The first can be considered as  
13  
14 suggested by O'Neill, with an approach trying to make use of the full skill set of the workers,  
15  
16 including their psychological and bodily functions (O'Neill 2017). The impact of cognitive and  
17  
18 behavioural sciences in this area was on the rise at the very moment at which progress in  
19  
20 specifically neurosciences started dominating the perception of the human body, and  
21  
22 psychological status was considered as something that can be transformed into mind-sets.  
23  
24 This hyper-positivist turn in psychology led to the study of what is called neuroergonomics,  
25  
26 defined as the study of brain and behaviour at work to align technological and human  
27  
28 capabilities with the aim to increase efficiency. The development of non-invasive  
29  
30 technologies and their wearability include the potential 'for monitoring human brain  
31  
32 function that can be used to study various aspects of human behaviour in relation to  
33  
34 technology and work, including mental workload, visual attention, working memory, motor  
35  
36 control, human-automation interaction, and adaptive automation' (Parasuraman & Rizzo  
37  
38 2007; Raduentz 2018).  
39  
40  
41  
42  
43  
44  
45  
46

47 Cognitive and behavioural sciences no longer relied on collected experimental knowledge-  
48  
49 they now had real-time feedback loops. In an introduction to a book on 'Automation and  
50  
51 behavioural sciences' the author states that '(t)he tremendous increase in automated  
52  
53 systems in the workplace seems to have caught the behavioural sciences unprepared.  
54  
55

56 Despite the almost common place use of automated systems in a variety of occupations,  
57  
58 there is only a small body of literature that has discussed the effects of these systems on  
59  
60

1  
2  
3 performance. In fact, it is only recently that social scientists have turned their attention to  
4  
5 this important aspect of performance. Consequently, the need to understand the degree to  
6  
7 which automation affects human performance in complex systems is becoming an urgent  
8  
9 topic for applied scientists' (Mouala 1996:21).  
10  
11  
12  
13

14  
15 With ever more developed technologies, the factory planner and work designer have more  
16  
17 and more tool available to overcome the obstacles of planning efficiently by surveilling  
18  
19 workers agency. The few papers engaging with this topic so far (Lemov 2018; Moore 2018a,  
20  
21 2018b), suggest that there is a strong continuation between early time-motion studies  
22  
23 (inspired by Taylor and Gilbreth) and the Human Relations approaches (Mayo, Müntzberg).<sup>vi</sup>  
24  
25 However, in this perspective the binary division between mind and muscles inspired by  
26  
27 Taylor seems to be reproduced. New technologies seem to be solely used to further control  
28  
29 workers, and to monitor new, so far invisible, and subjective information about the worker.  
30  
31 The idea of 'finding the right man for the right job', based on physical capabilities, simply  
32  
33 seems to be expanded to emotions and affects to be included to assess performance  
34  
35 (Moore 2017; 2018). New technologies quite rightly measure the impact of environmental  
36  
37 influences on performance and predict the areas for change, the worker becoming 'agile'  
38  
39 just as the work system (O'Neill 2017). But what about capturing the situated knowledge?  
40  
41 Empirical research so far has not fully engaged with the involvement of workers in  
42  
43 continuous improvement processes as part of today's performance management and target  
44  
45 driven work organisation (Taylor 2013). In the last section I will present some preliminary  
46  
47 findings from research within the German context and discuss the suggestions on how to  
48  
49 conceptualise what is known so far. In particular, I focus on the concept of 'cybernetic  
50  
51 control' (Butollo et al 2018) and how the value capture of situated knowledge might change  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 within cybernetic work systems and their ability to record, process, and feedback data down  
4  
5 to the micro ergonomic level.  
6  
7

### 8 9 **Welcome within the machine: Towards cybernetic control?**

10  
11  
12 While there is some empirical evidence for changes in manufacturing in the realm of  
13  
14 Industry 4.0 (Pfeiffer 2016), the implementation and use of wearables and real world CPS is  
15  
16 in its embryonic state still. In a recent publication focussing on how solution developers and  
17  
18 management frame and legitimate the implementation of new technologies, Evers et al  
19  
20 (2018) can show that the interviewed managers, though also driven by the idea to increase  
21  
22 efficiency, clearly engaged with their projects due to the incentives and initiatives by the  
23  
24 German government. With pilot studies funded and evaluated by independent researchers,  
25  
26 companies could showcase their innovative culture. New technologies in this respect seem  
27  
28 to be seen as a new 'must have' rather than fully integrated into management process  
29  
30 thinking so far. On the other hand, software developers were eager to marketise their new  
31  
32 products in underlining the benefits for the workers, and selling it to companies promising  
33  
34 'significant gains in ergonomics and production efficiency (that) can be achieved when work  
35  
36 process data is recorded and analysed comprehensively' (Evers et al 2018:18). They also  
37  
38 outlined new forms of labour control, and 'mentioned cases in which the technology would  
39  
40 recognize whether the employees showed up the first day after their holidays, or whether  
41  
42 they are currently working on a piece that was no longer a part of the production program'  
43  
44 (ibid). Software developers than pointed out how isolating the use of new technologies  
45  
46 could be in that they limit the possibilities to communicate. Evers at al (2018) present the  
47  
48 following quote underlining some of the potentials of wearables "Of course, I now have to  
49  
50 say that I no longer have to walk to the control room, and I cannot talk to my buddy in the  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 control room anymore—yes, actually that’s an issue.” (Solution Developer Germany LE-D-4).

4  
5 Decreasing autonomy and self responsibility – pillars of high performance work systems -  
6  
7  
8 seem to vanish, and so might the space for workers resistance. These conclusions are  
9  
10 supported by the findings presented by Butollo et al (2018) with the example of so called  
11  
12 ‘smart maintenance’ approaches based on predictive maintenance concepts. They can  
13  
14 observe a shift in the perception of how workers skills will be deployed. With systems now  
15  
16 based on data analytics maintenance personnel is reduced to simple tasks like exchanging  
17  
18 parts in a prescribed way. In their report, this is described by one interviewee as the fading  
19  
20 away of the ‘machine whisperer’ (Butollo et al 2018:15). What is to be observed here is the  
21  
22 change in occupational identity, but also a loss of collective power at work. Butollo et al  
23  
24 (2018) furthermore stress how the underlying assumptions are based on a strong  
25  
26 ‘technology-fixated’ approach to the implementation of new technologies. Organisations, as  
27  
28 they see it, would be in danger to lose the capacity for human-led problem solving  
29  
30 potentials in the case of system failure by cutting away experiential, or, as I would frame it,  
31  
32 situated knowledge (ibid). While the authors focus on how trade unions and workers’  
33  
34 councils could engage with these challenges in pushing for participation oriented  
35  
36 approaches, Raffetseder et al (2017) suggest to frame the use of new technologies with a  
37  
38 new form of control. As mentioned in the introduction, they see ‘cybernetic’ control in the  
39  
40 making, where top-down and outcome control is horizontalised and integrated in the  
41  
42 immediate workflow. Yet again, the potential of new technologies is underestimated when  
43  
44 focussing on control, autonomy, or discretion only. What is at stake is the equivalent of the  
45  
46 passing of situated knowledge to the next generations of workers, that has been a process  
47  
48 harnessed by capital for years, to create an ever more exchangeable workforce. In how far  
49  
50 this crucial point of resistance for workers can be upheld, how actually existing workfare  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 systems favour this type of work organisation (Briken & Taylor 2018), and what this means  
4  
5 for further collective action and strategies clearly needs some further empirical grounding.  
6  
7 But it seems important to take into account that new technologies have at least the  
8  
9 potential to increase efficiency with workers involuntarily while working delivering the  
10  
11 necessary information. The workers very own interactions with the system they are included  
12  
13 in are extracted, fed back and processed. Workers' situated knowledge, their tacit capital,  
14  
15 and emotions and affects are the more and more likely to be recorded and analysed for  
16  
17 future use and improvement (either on site or in factories elsewhere). The integration of  
18  
19 new technologies hence obscures how the transformation of labour into labour power is  
20  
21 actually taking place. Neither is there any directability of the machine, nor observability  
22  
23 (Morison and Woods 2016) on what the 'machine' is doing or learning from their moves or  
24  
25 affects, let alone how they contribute to improving the work system.  
26  
27  
28  
29

52 <sup>i</sup> I chose to borrow this term introduced by Donna Haraway (1988). I am aware of her using it from a critical  
53 feminist sociology of knowledge perspective. Situated knowlegde captures the embodied, complicated,  
54 actively seeing part of knowledge and connects it to time and space. Opposed to tacit knowledge, the concept  
55 insists and ontologises parts of human knowledge so closely connected to the human body that they can not  
56 made explicit. The concept follows a logic presented by Oskar Negt and Alexander Kluge (1973 [2014]) claiming  
57 that the experience of production is distinct from and incommensurable with its instruments or its product.  
58 While the related Obstinacy used withing the labour process is bound to experiences, Haraway connects it to  
59 knowledge production.

---

ii At the time of writing this paper we can observe a striking renaissance of national industrial strategies connected with the debates around 4.0 in Western European countries, and it would be worthwhile to consider the upcoming varieties of automation in the specific national contexts and how they might be considered as supporting the rise of nationalism (Briken 2017).

iii 4.0 relates to a linear version of industrial revolutions, the third being defined by the use of IT and ever more automated production. Though seeded within a paradigm based on manufacturing, the idea of 4.0 spread into services, with ideas like Business 4.0 (Volkswagen), Skills 4.0-Initiatives (Skills development Scotland), and Japan even moving towards a Society 5.0 already.

iv

v This observation was confirmed by my own empirical investigations and workplace observations on the shop floor in the German Chemical Industry in between 1997-1999.

vi See more recent academic paper by Lee and Lee (2018) on how cognitive sciences use ideas stemming from behavioural sciences pattern based on sophisticated stimuli models.
